

Unit 2 Study Guide (Lecture)

1. The skeletal system consists of bones, cartilage, ligaments, and tendons. Its main functions include providing support and structure to the body, protecting internal organs, facilitating movement, producing blood cells, and storing minerals.

2. The tissue types found in bone are:

- Osseous tissue (bone tissue): This is the main tissue in bones and provides strength and support. It is made up of cells called osteocytes and a matrix composed of collagen fibers and mineral salts.
- Cartilage tissue: This is a flexible connective tissue found in the joints, nose, ears, and other parts of the body. It provides a cushioning effect and helps with smooth movement.
- Dense connective tissue: This type of tissue forms the outer covering of bones, called periosteum, and provides protection and nourishment to the bone.

3. Bones can be classified into five major shapes:

- Long bones: These bones are longer than they are wide and have a shaft (diaphysis) and two ends (epiphyses). An example is the femur (thigh bone).
- Short bones: These bones are roughly equal in length and width, providing stability and support. An example is the carpals in the wrist.
- Flat bones: These bones are thin and often curved, providing protection to underlying organs. Examples include the skull bones and ribs.
- Irregular bones: These bones have complex shapes and do not fit into any other category. Examples include the vertebrae and facial bones.
- Sesamoid bones: These are small, round bones found within tendons. An example is the patella (kneecap).

4. Osseous tissue (bone tissue) is composed of specialized cells and a matrix. The cells include osteoblasts, which are responsible for bone formation, and osteoclasts, which break down and resorb bone. The matrix consists of collagen fibers, which provide flexibility, and mineral salts (calcium and phosphate), which provide strength and hardness.

Lacunae are small spaces within the bone matrix that contain osteocytes, which are mature bone cells. These cells maintain the bone tissue and help with the exchange of nutrients and waste products.

Canaliculi are small channels that connect the lacunae and allow for communication between osteocytes and the blood supply. This network of canaliculi ensures that all bone cells receive necessary nutrients and oxygen.

The significance of lacunae and canaliculi is that they allow for the exchange of nutrients, waste products, and signals between cells, promoting the overall health and function of the bone tissue.

5. Compact bone and spongy bone are two types of bone tissue found in different parts of the bone.

Compact bone, also known as cortical bone, is dense and forms the outer layer of most bones. It provides strength and protection. It is composed of concentric layers of bone tissue called lamellae, which surround central canals that contain blood vessels and nerves. The arrangement of lamellae and canals creates a characteristic haversian system or osteon.
