

A shield volcano is named because of its low profile resembling a warrior's shield laid on the ground. Shield volcanoes are formed by the eruption of highly fluid low viscosity lava (which results from partial melting) flows that the lava doesn't get stopped from a

The way that a volcano gets its shape is determined by the lava. Shield volcanoes have low viscosity lava, described as being basaltic. Shield volcanoes' low viscosity lava means that the lava is more liquid and flows more quickly than thick lava. The sides of these volcanoes are gentle rather than being steep, as the lava travels a long distance before it solidifies. These volcanoes are easily recognisable as being wider than they are tall.

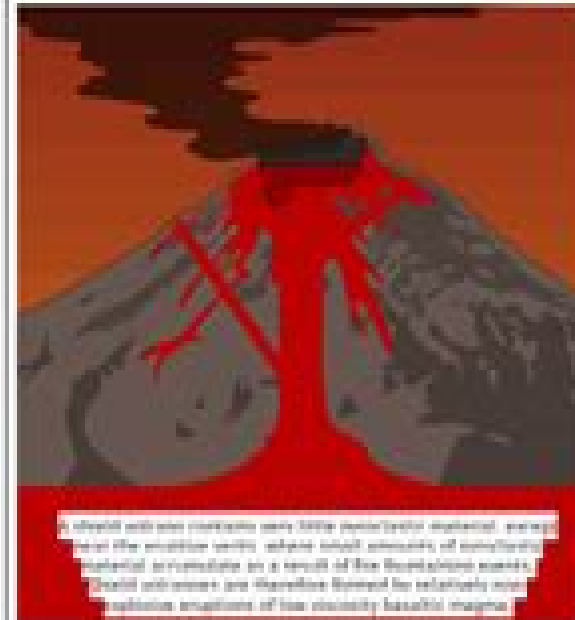

When a shield volcano erupts, it is only explosive if some substance gets into the vent, otherwise they are characterised by low explosivity forming that forms cinder cones and spatter cones at the vent. However, 80% of the volume is lava rather than pyroclastic material.
